ABSTRACT

Recently, Kitaev and Remmel [8] refined the well-known permutation statistic “descent” by fixing parity of one of the descent’s numbers. Results in [8] were extended and generalized in several ways in [7, 9, 10, 11]. In this paper, we shall fix a set partition of the natural numbers \mathbb{N} , $(\mathbb{N}_1, \dots, \mathbb{N}_t)$, and we study the distribution of descents, levels, and rises according to whether the first letter of the descent, rise, or level lies in \mathbb{N}_i over the set of words over the alphabet $[k] = \{1, \dots, k\}$. In particular, we refine and generalize some of the results in [4].

1. INTRODUCTION

The descent set of a permutation $\pi = \pi_1 \dots \pi_n \in S_n$ is the set of indices i for which $\pi_i > \pi_{i+1}$. This statistic was first studied by MacMahon [12] almost a hundred years ago and it still plays an important role in the field of permutation statistics. The number of permutations of length n with exactly m descents is counted by the *Eulerian number* $A_m(n)$. The Eulerian numbers are the coefficients of the *Eulerian polynomials* $A_n(t) = \sum_{\pi \in S_n} t^{1+\text{des}(\pi)}$. It is well-known that the Eulerian polynomials satisfy the identity $\sum_{m \geq 0} m^n t^m = \frac{A_n(t)}{(1-t)^{n+1}}$. For more properties of the Eulerian polynomials see [5].

Recently, Kitaev and Remmel [8] studied the distribution of a refined “descent” statistic on the set of permutations by fixing parity of (exactly) one of the descent’s numbers. For example, they showed that the number of permutations in S_{2n} (resp. S_{2n+1}) with exactly k descents such that the first entry of the descent is an even number is given by $\binom{n}{k}^2 n!^2$ (resp. $\frac{1}{k+1} \binom{n}{k}^2 (n+1)!^2$). In [9], the authors generalized results of [8] by studying descents according to whether the first or the second element in a descent pair is equivalent to $0 \pmod{k \geq 2}$.

Consequently, Hall and Remmel [7] generalized results of [9] by considering “ X, Y -descents,” which are descents whose “top” (first element) is in X and whose “bottom” (second element) is in Y where X and Y are

any sets of the natural number \mathbb{N} . In particular, Hall and Remmel [7] showed that one can reduce the problem of counting the number of permutations σ with k X, Y -descents to the problem of computing the k -th hit number of a Ferrers board in many cases. Liese [10] also considered the situation of fixing equivalence classes of both descent numbers simultaneously. Also, papers [6] and [11] discuss q -analogues of some of the results in [7, 8, 9, 10].

Hall and Remmel [7] extended their results on counting permutations with a given number of X, Y -descents to words. That is, let $R(\rho)$ be the rearrangement class of the word $1^{\rho_1} 2^{\rho_2} \dots m^{\rho_m}$ (i.e., ρ_1 copies of 1, ρ_2 copies of 2, etc.) where $\rho_1 + \dots + \rho_m = n$. For any set $X \subseteq \mathbb{N}$ and any set $[m] = \{1, 2, \dots, m\}$, we let $X_m = X \cap [m]$ and $X_m^c = [m] - X$. Then given $X, Y \subseteq \mathbb{N}$ and a word $w = w_1 \dots w_n \in R(\rho)$, define

$$Des_{X,Y}(w) = \{i : w_i > w_{i+1} \& w_i \in X \& w_{i+1} \in Y\},$$

$$des_{X,Y}(w) = |Des_{X,Y}(w)|, \text{ and}$$

$$P_{\rho,s}^{X,Y} = |\{w \in R(\rho) : des_{X,Y}(w) = s\}|.$$

Hall and Remmel [7] proved the following theorem by purely combinatorial means.

Theorem 1.1.

$$(1.1) \quad P_{\rho,s}^{X,Y} = \binom{a}{\rho_{v_1}, \rho_{v_2}, \dots, \rho_{v_b}} \sum_{r=0}^s (-1)^{s-r} \binom{a+r}{r} \binom{n+1}{s-r} \prod_{x \in X} \binom{\rho_x + r + \alpha_{X,\rho,x} + \beta_{Y,\rho,x}}{\rho_x},$$

where $X_m^c = \{v_1, v_2, \dots, v_b\}$, $a = \sum_{i=1}^b \rho_{v_i}$, and for any $x \in X_m$,

$$\begin{aligned} \alpha_{X,\rho,x} &= \sum_{\substack{z \notin X \\ x < z \leq m}} \rho_z, \text{ and} \\ \beta_{Y,\rho,x} &= \sum_{\substack{z \notin Y \\ 1 \leq z < x}} \rho_z. \end{aligned}$$

In this paper, we shall study similar statistics over the set $[k]^n$ of n -letter words over fixed finite alphabet $[k] = \{1, 2, \dots, k\}$. In what follows, $E = \{2, 4, 6, \dots\}$ and $O = \{1, 3, 5, \dots\}$ are the sets of even and odd numbers respectively. Also, we let $\mathbf{x}[t] = (x_1, \dots, x_t)$. Then given a word $\pi = \pi_1 \pi_2 \dots \pi_n \in [k]^n$ and a set $X \subseteq \mathbb{N}$, we define the following statistics:

- $\overleftarrow{\text{Des}}_X(\pi) = \{i : \pi_i > \pi_{i+1} \text{ and } \pi_i \in X\}$ and $\overleftarrow{\text{des}}_X(\pi) = |\overleftarrow{\text{Des}}_X(\pi)|$,
- $\overleftarrow{\text{Ris}}_X(\pi) = \{i : \pi_i < \pi_{i+1} \text{ and } \pi_i \in X\}$ and $\overleftarrow{\text{ris}}_X(\pi) = |\overleftarrow{\text{Ris}}_X(\pi)|$,
- $\text{Lev}_X(\pi) = \{i : \pi_i = \pi_{i+1} \text{ and } \pi_i \in X\}$ and $\text{lev}_X(\pi) = |\text{Lev}_X(\pi)|$.

Let $(\mathbb{N}_1, \dots, \mathbb{N}_t)$ be a set partition of the natural numbers \mathbb{N} , i.e. $\mathbb{N} = \mathbb{N}_1 \cup \mathbb{N}_2 \cup \dots \cup \mathbb{N}_t$ and $\mathbb{N}_i \cap \mathbb{N}_j = \emptyset$ for $i \neq j$. Then the main goal of this paper is to study the following multivariate generating function (MGF)

$$(1.2) \quad A_k = A_k(\mathbf{x}[t]; \mathbf{y}[t]; \mathbf{z}[t]; \mathbf{q}[t]) = \sum_{\pi} \prod_{i=1}^t x_i^{\overleftarrow{\text{des}}_{\mathbb{N}_i}(\pi)} y_i^{\overleftarrow{\text{ris}}_{\mathbb{N}_i}(\pi)} z_i^{\text{lev}_{\mathbb{N}_i}(\pi)} q_i^{i(\pi)}$$

where $i(\pi)$ is the number of letters from \mathbb{N}_i in π and the sum is over all words over $[k]$.

The outline of this paper is as follows. In section 2, we shall develop some general methods to compute (1.2). In section 3, we shall concentrate on the computing generating functions for the distribution of the number of levels. That is, we shall study A_k where set $x_i = y_i = 1$ for all i . In section 4, we shall find formulas for the number of words in $[k]^n$ that have s descents that start with an element less than or equal to t (greater than t) for any $t \leq k$. Note that if we replace a word $w = w_1 \cdots w_n \in [k]^n$ by its complement $w^c = (k+1-w_1) \cdots (k+1-w_n)$, then it is easy to see that $\overleftarrow{\text{des}}_{[t]}(w) = \overleftarrow{\text{ris}}_{\{k+1-t, \dots, k\}}(w)$ and $\overleftarrow{\text{des}}_{\{t+1, \dots, k\}}(w) = \overleftarrow{\text{ris}}_{[k-t]}(w)$. Thus we will also obtain formulas for the the number of words in $[k]^n$ that have s rises that start with an element less than or equal to t (greater than t) for any $t \leq k$. We will also show that in the cases where $t = 2$ or $t = k - 1$, there are alternative ways to compute our formulas which lead to non-trivial binomial identities. In section 5, we shall apply our results to study the problem of counting the number of words in $[k]^n$ with p descents (rises) that start with an element which is equivalent to $i \pmod{s}$ for any $s \geq 2$ and $i = 1, \dots, s$. In particular, if $s \geq 2$ and $(\mathbb{N}_1, \dots, \mathbb{N}_s)$ is the set partition of \mathbb{N} where $\mathbb{N}_i = \{x \in \mathbb{N} : x \equiv i \pmod{s}\}$ for $i = 1, \dots, s$, then we shall study the generating functions

$$(1.3) \quad A_k^{(s)}(\mathbf{x}[s]; \mathbf{y}[s]; \mathbf{z}[s]; \mathbf{q}[s]) = \sum_{\pi} \prod_{i=1}^s x_i^{\overleftarrow{\text{des}}_{\mathbb{N}_i}(\pi)} y_i^{\overleftarrow{\text{ris}}_{\mathbb{N}_i}(\pi)} z_i^{\text{lev}_{\mathbb{N}_i}(\pi)} q_i^{i(\pi)}$$

and

$$(1.4) \quad A_k^{(s)}(\mathbf{x}[s]; \mathbf{y}[s]; \mathbf{z}[s]; q) = \sum_{\pi} q^{|\pi|} \prod_{i=1}^s x_i^{\overleftarrow{\text{des}}_{\mathbb{N}_i}(\pi)} y_i^{\overleftarrow{\text{ris}}_{\mathbb{N}_i}(\pi)} z_i^{\text{lev}_{\mathbb{N}_i}(\pi)}.$$

Our general results in section 2 allow us to derive an explicit formula for $A_k^{(s)}(\mathbf{x}[s]; \mathbf{y}[s]; \mathbf{z}[s]; \mathbf{q}[s])$ depending on the equivalence class of $k \pmod{s}$.

For example, in the case where $s = 2$, our general result implies that

$$(1.5) \quad \begin{aligned} A_{2k}^{(2)}(q_1, q_2) &= A_k(x_1, x_2, y_1, y_2, z_1, z_2, q_1, q_2) = \\ &= \sum_{\pi} x_1^{\overleftarrow{\text{des}}_O(\pi)} x_2^{\overleftarrow{\text{des}}_E(\pi)} y_1^{\overleftarrow{\text{ris}}_O(\pi)} y_2^{\overleftarrow{\text{ris}}_E(\pi)} z_1^{\text{lev}_O(\pi)} z_2^{\text{lev}_E(\pi)} q_1^{\text{odd}(\pi)} q_2^{\text{even}(\pi)} \\ &= \frac{1 + (\lambda_1 \mu_2 + \lambda_2) \frac{1 - \mu_1^k \mu_2^k}{1 - \mu_1 \mu_2}}{1 - (\nu_1 \mu_2 + \nu_2) \frac{1 - \mu_1^k \mu_2^k}{1 - \mu_1 \mu_2}} \end{aligned}$$

where the sum is over all words over $[2k]$, $\text{even}(\pi)$ (resp. $\text{odd}(\pi)$) is the number of even (resp. odd) numbers in π , $\lambda_j = \frac{q_j(1-y_j)}{1-q_j(z_j-y_j)}$, $\mu_i = \frac{q_i(z_i-x_i)}{1-q_i(z_i-y_i)}$, and $\nu_j = \frac{q_j y_j}{1-q_j(z_j-y_j)}$ for $j = 1, 2$. Then by specializing the variables appropriately, we will find explicit formulas for the number of words $w \in [2k]^n$ such that $\overleftarrow{\text{des}}_E(\pi) = p$, $\overleftarrow{\text{des}}_O(\pi) = p$, $\overleftarrow{\text{ris}}_E(\pi) = p$, $\overleftarrow{\text{ris}}_O(\pi) = p$, etc. For example, we prove that the number of n -letter words π on $[2k]$ having $\overleftarrow{\text{des}}_O(\pi) = p$ (resp. $\overleftarrow{\text{ris}}_E(\pi) = p$) is given by

$$\sum_{j=0}^n \sum_{i=0}^j (-1)^{n+p+i} 2^j \binom{j}{i} \binom{i}{n} \binom{n-j}{p}.$$

In fact, we shall show that similar formulas hold for the number of words $\pi \in [k]^n$ with p descents (rises, levels) whose first element is equivalent to $t \pmod{s}$ for any $s \geq 2$ and $0 \leq t \leq s-1$. Our results refine and generalize the results in [4] related to the distribution of descents, levels, and rises in words. Finally, in section 6, we shall discuss some open questions and further research.

2. THE GENERAL CASE

We need the following notation:

$$A_k(i_1, \dots, i_m) = A_k(\mathbf{x}[t]; \mathbf{y}[t]; \mathbf{z}[t]; \mathbf{q}[t]; \mathbf{i}[m]) = \sum_{\pi} \prod_{i=1}^t x_i^{\overleftarrow{\text{des}}_{\mathbb{N}_i}(\pi)} y_i^{\overleftarrow{\text{ris}}_{\mathbb{N}_i}(\pi)} z_i^{\text{lev}_{\mathbb{N}_i}(\pi)} q_i^{i(\pi)}$$

where the sum is taken over all words $\pi = \pi_1 \pi_2 \dots$ over $[k]$ such that $\pi_1 \dots \pi_m = i_1 \dots i_m$.

From our definitions, we have that

$$(2.1) \quad A_k = 1 + \sum_{i=1}^k A_k(i).$$

Thus, to find a formula for A_k , it is sufficient to find a formula for $A_k(i)$ for each $i = 1, 2, \dots, k$. First let us find a recurrence relation for the generating function $A_k(i)$.

Lemma 2.1. *For each $s \in \mathbb{N}_i$, $1 \leq s \leq k$ and $1 \leq i \leq t$, we have*

$$(2.2) \quad A_k(s) = \frac{q_i y_i}{1 - q_i(z_i - y_i)} A_k + \frac{q_i(1 - y_i)}{1 - q_i(z_i - y_i)} + \frac{q_i(x_i - y_i)}{1 - q_i(z_i - y_i)} \sum_{j=1}^{s-1} A_k(j).$$

Proof. From the definitions we have that

$$\begin{aligned} A_k(s) &= q_i + \sum_{j=1}^k A_k(s, j) \\ &= q_i + \sum_{j=1}^{s-1} A_k(s, j) + A_k(s, s) + \sum_{j=s+1}^k A_k(s, j). \end{aligned}$$

Let π be any n -letter word over $[k]$ where $n \geq 2$ and $\pi_1 = s > \pi_2 = j$. If we let $\pi' = \pi_2 \pi_3 \dots \pi_n$, then it is easy to see that

$$\overleftarrow{\text{des}}_{\mathbb{N}_i}(\pi) = 1 + \overleftarrow{\text{des}}_{\mathbb{N}_i}(\pi'), \quad i(\pi) = 1 + i(\pi').$$

It is also easy to see that remaining $4t - 2$ statistics of interest take the same value on π and π' .

This implies that $A_k(s, j) = q_i x_i A_k(j)$ for each $1 \leq j < s$. Similarly, $A_k(s, s) = q_i z_i A_k(s)$ and $A_k(s, j) = q_i y_i A_k(j)$ for $s < j \leq k$. Therefore,

$$A_k(s) = q_i + q_i x_i \sum_{j=1}^{s-1} A_k(j) + q_i z_i A_k(s) + q_i y_i \sum_{j=s+1}^k A_k(j).$$

Using (2.1), we have $\sum_{j=s+1}^k A_k(j) = A_k - \sum_{j=1}^{s-1} A_k(j) - A_k(s) - 1$, and thus

$$A_k(s) = \frac{q_i y_i}{1 - q_i(z_i - y_i)} A_k + \frac{q_i(1 - y_i)}{1 - q_i(z_i - y_i)} + \frac{q_i(x_i - y_i)}{1 - q_i(z_i - y_i)} \sum_{j=1}^{s-1} A_k(j),$$

as desired. \square

Lemma 2.2. *For each $k \geq 1$ and $s \in [k]$,*

$$(2.3) \quad \sum_{j=1}^s A_k(j) = \sum_{j=1}^s \gamma_j \prod_{i=j+1}^s (1 - \alpha_i)$$

where, for $i \in \mathbb{N}_m$ and $i \geq 1$, $\gamma_i = \frac{q_m y_m}{1 - q_m(z_m - y_m)} A_k + \frac{q_m(1 - y_m)}{1 - q_m(z_m - y_m)}$ and $\alpha_i = \frac{q_m(y_m - x_m)}{1 - q_m(z_m - y_m)}$.

Proof. We proceed by induction on s . Note, that given our definitions of γ_i and α_i , we can rewrite (2.2) as

$$(2.4) \quad A_k(s) = \gamma_s - \alpha_s \sum_{j=1}^{s-1} A_k(j).$$

It follows that

$$A_k(1) = \gamma_1$$

so that (2.3) holds for $s = 1$. Thus the base case of our induction holds. Now assume that (2.3) holds for s where $1 \leq s < k$. Then using our induction hypothesis and (2.4), it follows that

$$\begin{aligned} & A_k(1) + \cdots + A_k(s) + A_k(s+1) \\ &= \sum_{j=1}^s \gamma_j \prod_{i=j+1}^s (1 - \alpha_i) + \gamma_{s+1} - \alpha_{s+1} \left(\sum_{j=1}^s \gamma_j \prod_{i=j+1}^s (1 - \alpha_i) \right) \\ &= \gamma_{s+1} - \sum_{j=1}^s \gamma_j \prod_{i=j+1}^{s+1} (1 - \alpha_i) \\ &= \sum_{j=1}^{s+1} \gamma_j \prod_{i=j+1}^{s+1} (1 - \alpha_i). \end{aligned}$$

Thus the induction step also holds so that (2.3) must hold in general. \square

Lemma 2.1 gives that $A_k(i)$, for $1 \leq i \leq k$, are the solution to the following matrix equation

$$(2.5) \quad \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & \dots & 0 \\ \alpha_2 & 1 & 0 & 0 & 0 & \dots & 0 \\ \alpha_3 & \alpha_3 & 1 & 0 & 0 & \dots & 0 \\ \alpha_4 & \alpha_4 & \alpha_4 & 1 & 0 & \dots & 0 \\ \vdots & & & & & \ddots & \\ \alpha_k & \alpha_k & \alpha_k & \alpha_k & \alpha_k & \dots & 1 \end{pmatrix} \cdot \begin{pmatrix} A_k(1) \\ A_k(2) \\ \vdots \\ A_k(k) \end{pmatrix} = \begin{pmatrix} \gamma_1 \\ \gamma_2 \\ \vdots \\ \gamma_k \end{pmatrix}$$

where, for $i \in \mathbb{N}_m$ and $i \geq 1$, $\gamma_i = \frac{q_m y_m}{1 - q_m(z_m - y_m)} A_k + \frac{q_m(1 - y_m)}{1 - q_m(z_m - y_m)}$, and, for $i \in \mathbb{N}_m$ and $i \geq 2$, $\alpha_i = \frac{q_m(y_m - x_m)}{1 - q_m(z_m - y_m)}$. Notice that $\alpha_i = \alpha_j$ and $\gamma_i = \gamma_j$ whenever i and j are from the same set \mathbb{N}_m for some m . In fact, it is easy to see that (2.2) and (2.3) imply that

$$(2.6) \quad A_k(i) = \gamma_i - \alpha_i \sum_{j=1}^{i-1} \gamma_j \prod_{i=j+1}^{i-1} (1 - \alpha_i)$$

holds for $i = 1, \dots, k$ so that (2.5) has an explicit solution. By combining (2.1) and (2.6), we can obtain the following result.

Theorem 2.3. *For α_i and γ_i as above (defined right below (2.5)), we have*

$$A_k = 1 + \sum_{j=1}^k \gamma_j \prod_{i=j+1}^k (1 - \alpha_i)$$

solving which for A_k gives

$$(2.7) \quad A_k = \frac{1 + \sum_{j=1}^k \frac{q_j(1-y_j)}{1-q_j(z_j-y_j)} \prod_{i=j+1}^k \frac{1-q_i(z_i-x_i)}{1-q_i(z_i-y_i)}}{1 - \sum_{j=1}^k \frac{q_j y_j}{1-q_j(z_j-y_j)} \prod_{i=j+1}^k \frac{1-q_i(z_i-x_i)}{1-q_i(z_i-y_i)}}$$

where for each variable $a \in \{x, y, z, q\}$ we have $a_i = a_m$ if $i \in \mathbb{N}_m$.

Even though we state Theorem 2.3 as the main theorem in this paper, its statement can be (easily) generalized if one considers compositions instead of words. Indeed, let

$$B_k = B_k(\mathbf{x}[t]; \mathbf{y}[t]; \mathbf{z}[t]; \mathbf{q}[t]; v) = \sum_{\pi} v^{|\pi|} \prod_{i=1}^t x_i^{\overleftarrow{\text{des}}_{\mathbb{N}_i}(\pi)} y_i^{\overleftarrow{\text{ris}}_{\mathbb{N}_i}(\pi)} z_i^{\text{lev}_{\mathbb{N}_i}(\pi)} q_i^{i(\pi)}$$

where the sum is taken over all compositions $\pi = \pi_1 \pi_2 \dots$ with parts in $[k]$ and $|\pi| = \pi_1 + \pi_2 + \dots$ is the weight of the composition π . Also, we let

$$B_k(i_1, \dots, i_m) = B_k(\mathbf{x}[t]; \mathbf{y}[t]; \mathbf{z}[t]; \mathbf{q}[t]; \mathbf{i}[m]; v) = \sum_{\pi} v^{|\pi|} \prod_{i=1}^t x_i^{\overleftarrow{\text{des}}_{\mathbb{N}_i}(\pi)} y_i^{\overleftarrow{\text{ris}}_{\mathbb{N}_i}(\pi)} z_i^{\text{lev}_{\mathbb{N}_i}(\pi)} q_i^{i(\pi)}$$

where again the sum is taken over all compositions $\pi = \pi_1 \pi_2 \dots$ with parts in $[k]$.

Next, one can copy the arguments of Lemma 2.1 substituting q_i by $v^s q_i$ to obtain the following generalization of Lemma 2.1:

$$B_k(s) = \frac{v^s q_i y_i}{1 - q_i(z_i - y_i)} B_k + \frac{v^s q_i (1 - y_i)}{1 - q_i(z_i - y_i)} + \frac{v^s q_i (x_i - y_i)}{1 - q_i(z_i - y_i)} \sum_{j=1}^{s-1} B_k(j).$$

One can then prove the obvious analogue of Lemma 2.1 by induction and apply it to prove the following theorem.

Theorem 2.4. *We have*

$$B_k = 1 + \sum_{j=1}^k \gamma_j \prod_{i=j+1}^k (1 - \alpha_i)$$

where $\gamma_i = \frac{v^i q_m y_m}{1 - q_m(z_m - y_m)} B_k + \frac{v^i q_m (1 - y_m)}{1 - q_m(z_m - y_m)}$, and $\alpha_i = \frac{v^i q_m (y_m - x_m)}{1 - q_m(z_m - y_m)}$ if i belongs to \mathbb{N}_m . Thus,

$$B_k = \frac{1 + \sum_{j=1}^k \frac{v^j q_j (1 - y_j)}{1 - q_j(z_j - y_j)} \prod_{i=j+1}^k \frac{1 - q_i(z_i - y_i + v^i(y_i - x_i))}{1 - q_i(z_i - y_i)}}{1 - \sum_{j=1}^k \frac{v^j q_j y_j}{1 - q_j(z_j - y_j)} \prod_{i=j+1}^k \frac{1 - q_i(z_i - y_i + v^i(y_i - x_i))}{1 - q_i(z_i - y_i)}}$$

where for each variable $a \in \{x, y, z, q\}$ we have $a_i = a_m$ if $i \in \mathbb{N}_m$.

Theorem 2.4 can be viewed as a q -analogue to Theorem 2.3. (Set $v = 1$ in Theorem 2.4 to get Theorem 2.3.)

3. COUNTING WORDS BY THE TYPES OF LEVELS

Suppose we are given a set partition $\mathbb{N} = \mathbb{N}_1 \cup \mathbb{N}_2 \cup \dots \cup \mathbb{N}_s$. First observe that for any fixed i , if we want the distribution of words in $[k]^n$ according to the number of levels which involve elements in \mathbb{N}_i , then it is easy to see by symmetry that the distribution will depend only on the cardinality of $\mathbb{N}_i \cap [k]$. Thus we only need to consider the case where $s = 2$ and $\mathbb{N}_1 = \{1, \dots, t\}$ for some $t \leq k$.

Let

$$(3.1) \quad \lambda_j = \frac{q_j(1 - y_j)}{1 - q_j(z_j - y_j)},$$

$$(3.2) \quad \nu_j = \frac{q_j y_j}{1 - q_j(z_j - y_j)}, \text{ and}$$

$$(3.3) \quad \mu_i = \frac{1 - q_i(z_i - x_i)}{1 - q_i(z_i - y_i)}.$$

Then we can rewrite (2.7) for any arbitrary set partition $\mathbb{N} = \mathbb{N}_1 \cup \mathbb{N}_2 \cup \dots \cup \mathbb{N}_s$ as

$$(3.4) \quad A_k = \frac{1 + \sum_{j=1}^k \lambda_j \prod_{i=j+1}^k \mu_i}{1 - \sum_{j=1}^k \nu_j \prod_{i=j+1}^k \mu_i}$$

where for each variable $a \in \{x, y, z, q\}$, we have $a_i = a_m$ if $i \in \mathbb{N}_m$.

Suppose we set $x_1 = x_2 = y_1 = y_2 = z_2 = 1$ and $q_1 = q_2 = q$ in (3.4) in the special case where $s = 2$ and $\mathbb{N}_1 = [t]$ for some $t \leq k$. Then $\lambda_1 = \lambda_2 = 0$, $\nu_1 = \frac{q}{1-q(z_1-1)}$, $\nu_2 = q$, and $\mu_1 = \mu_2 = 1$. It follows that in this case,

$$\begin{aligned} A_k &= \frac{1}{1 - \left(\frac{tq}{1-q(z_1-1)} + q(k-t) \right)} \\ &= \sum_{m \geq 0} q^m \left(\frac{t}{1-q(z_1-1)} + (k-t) \right)^m \\ &= \sum_{m \geq 0} q^m \sum_{i=0}^m \binom{m}{i} (k-t)^{m-i} t^i \left(\frac{1}{1-q(z_1-1)} \right)^i. \end{aligned}$$

Since

$$\begin{aligned} \left(\frac{1}{1-q(z_1-1)} \right)^i &= \sum_{a \geq 0} \frac{(i)_a}{a!} q^a (z_1-1)^a \\ (3.5) \quad &= \sum_{a \geq 0} \binom{i+a-1}{a} q^a (z_1-1)^a, \end{aligned}$$

it follows that

$$(3.6) \quad A_k = \sum_{n \geq 0} q^n \sum_{m=0}^n \sum_{i=0}^m \binom{m}{i} \binom{i+n-m-1}{n-m} (k-t)^{m-i} t^i (z_1-1)^{n-m}.$$

Thus taking the coefficient of z_1^s on both sides of (3.6), we obtain the following result.

Theorem 3.1. *Let $\mathbb{N} = \mathbb{N}_1 \cup \mathbb{N}_2$ where $\mathbb{N}_1 = [t]$ and $\mathbb{N}_2 = \mathbb{N} - \mathbb{N}_1$. Then if $t \leq k$, the number of words in $[k]^n$ with s levels that start with elements in \mathbb{N}_1 is*

$$(3.7) \quad \sum_{m=0}^n \sum_{i=0}^m (-1)^{n-m-s} \binom{m}{i} \binom{i+n-m-1}{n-m} \binom{n-m}{s} (k-t)^{m-i} t^i.$$

Going back to the general set partition $\mathbb{N} = \mathbb{N}_1 \cup \mathbb{N}_2 \cup \dots \cup \mathbb{N}_s$, we can obtain a general formula for the number of words in $[k]^n$ for which there are t_i levels which start with an element of \mathbb{N}_i for $i = 1, \dots, s$ as

follows. Let $n_i = |\mathbb{N}_i \cap [k]|$ for $i = 1, \dots, n$. Then if set $x_j = y_j = 1$ and $q_j = q$ for all j , then it will be the case that $\lambda_j = 0$ and $\mu_j = 1$ and $\nu_j = \frac{q}{1-q(z_j-1)}$ for all j . It easy follows that in this case,

$$\begin{aligned} A_k &= \frac{1}{1 - \left(\sum_{i=1}^s \frac{n_i q}{1-q(z_i-1)} \right)} \\ &= \sum_{m \geq 0} q^m \left(\sum_{i=1}^s \frac{n_i}{1-q(z_i-1)} \right)^m \\ &= \sum_{m \geq 0} q^m \sum_{\substack{a_1 + \dots + a_s = m \\ a_1, \dots, a_s \geq 0}} \binom{m}{a_1, \dots, a_m} \prod_{i=1}^s \left(\frac{n_i}{1-q(z_i-1)} \right)^{a_i}. \end{aligned}$$

Then using (3.5), we see that

$$\begin{aligned} A_k &= \sum_{m \geq 0} q^m \sum_{\substack{a_1 + \dots + a_s = m \\ a_1, \dots, a_s \geq 0}} \binom{m}{a_1, \dots, a_m} n_1^{a_1} \cdots n_s^{a_s} \prod_{i=1}^s \sum_{b_i \geq 0} \frac{(a_i)_{b_i}}{b_i!} q^{b_i} (z_1 - 1)^{b_i} \\ (3.8) \quad &= \sum_{n \geq 0} q^n \sum_{m=0}^n \sum_{\substack{a_1 + \dots + a_s = m \\ a_1, \dots, a_s \geq 0}} \sum_{\substack{b_1 + \dots + b_s = n-m \\ b_1, \dots, b_s \geq 0}} \binom{m}{a_1, \dots, a_m} n_1^{a_1} \cdots n_s^{a_s} \prod_{i=1}^s \binom{a_i + b_i - 1}{b_i} (z_i - 1)^{b_i}. \end{aligned}$$

Taking the coefficient of $z_1^{t_1} \cdots z_s^{t_s}$ on both sides of (3.8), we obtain the following result.

Theorem 3.2. *Let $\mathbb{N} = \mathbb{N}_1 \cup \dots \cup \mathbb{N}_s$ be a set partition of \mathbb{N} . Let $n_i = |\mathbb{N}_i \cap [k]|$ for $i = 1, \dots, s$. Then the number of words in $[k]^n$ with t_i levels that start with elements in \mathbb{N}_i for $i = 1, \dots, s$ is*

$$(3.9) \quad \sum_{m=0}^n \sum_{\substack{a_1 + \dots + a_s = m \\ a_1, \dots, a_s \geq 0}} \sum_{\substack{b_1 + \dots + b_s = n-m \\ b_1, \dots, b_s \geq 0}} \binom{m}{a_1, \dots, a_m} n_1^{a_1} \cdots n_s^{a_s} \prod_{i=1}^s \binom{a_i + b_i - 1}{b_i} \binom{b_i}{t_i}.$$

4. CLASSIFYING WORDS BY THE NUMBER OF DESCENTS THAT START WITH ELEMENTS $\leq t$ ($\geq t+1$).

In this section, we shall consider the set partition $\mathbb{N} = \mathbb{N}_1 \cup \mathbb{N}_2$ where $\mathbb{N}_1 = [t]$. Now if $t \leq k$, then it is easy to see that we can rewrite (2.7) as

$$(4.1) \quad A_k = \frac{1 + \sum_{j=1}^k \lambda_j \prod_{i=j+1}^k \mu_i}{1 - \sum_{j=1}^k \nu_j \prod_{i=j+1}^k \mu_i}$$

where

$$\lambda_j = \frac{q_1(1-y_1)}{1-q_1(z_1-y_1)}, \quad \nu_j = \frac{q_1y_1}{1-q_1(z_1-y_1)}, \text{ and } \mu_j = \frac{q_1(z_1-x_1)}{1-q_1(z_1-y_1)} \text{ if } j \leq t$$

and

$$\lambda_j = \frac{q_2(1-y_2)}{1-q_2(z_2-y_2)}, \quad \nu_j = \frac{q_2y_2}{1-q_2(z_2-y_2)}, \text{ and } \mu_j = \frac{q_2(z_2-x_2)}{1-q_2(z_2-y_2)} \text{ if } j > t.$$

Now if we want to find formulas for the number of words in $[k]^n$ with s descents that start with an element less than or equal to t , then we need to set $x_2 = y_1 = y_2 = z_1 = z_2 = 1$ and $q_1 = q_2 = q$ in (4.1). In that

case, we will have $\lambda_j = 0$ and $\nu_j = q$ for all j , $\mu_j = 1 + q(x_1 - 1)$ for $j \leq t$, and $\mu_j = 1$ for $j > t$. It follows that

$$\begin{aligned}
A_k &= \frac{1}{1 - \left(\sum_{j=t+1}^k q + \sum_{j=1}^t q \prod_{i=j+1}^t (1 + q(x_1 - 1)) \right)} \\
&= \frac{1}{1 - \left((k-t)q + q \frac{(1+q(x_1-1))^t - 1}{(1+q(x_1-1))-1} \right)} \\
&= \frac{1}{1 - \frac{1}{(x_1-1)} ((k-t)q(x_1-1) - 1 + (1+q(x_1-1))^t)} \\
&= \sum_{m \geq 0} \frac{1}{(x_1-1)^m} ((k-t)q(x_1-1) - 1 + (1+q(x_1-1))^t)^m \\
&= \sum_{m \geq 0} \frac{1}{(x_1-1)^m} \sum_{a=0}^m \binom{m}{a} ((k-t)q(x_1-1) - 1)^{m-a} (1+q(x_1-1))^{ta} \\
&= \sum_{m \geq 0} \frac{1}{(x_1-1)^m} \sum_{a=0}^m \sum_{b=0}^{m-a} \sum_{c=0}^{ta} \binom{m}{a} \binom{m-a}{b} \binom{ta}{c} (-1)^{m-a-b} q^b (k-t)^b (x_1-1)^b q^c (x_1-1)^c.
\end{aligned}$$

If we want to take the coefficient of q^n , then we must have $b+c=n$ or $c=n-b$. Thus

$$(4.2) \quad A_k = \sum_{n \geq 0} q^n \sum_{m \geq 0} \sum_{a=0}^m \sum_{b=0}^{m-a} \binom{m}{a} \binom{m-a}{b} \binom{ta}{n-b} (-1)^{m-a-b} (k-t)^b (x_1-1)^{n-m}.$$

Taking the coefficient of q^n of both sides of (4.2), we see that

$$(4.3) \quad \sum_{\pi \in [k]^n} x_1^{\overleftarrow{\text{des}}_{[t]}(\pi)} = \sum_{m \geq 0} \sum_{a=0}^m \sum_{b=0}^{m-a} \binom{m}{a} \binom{m-a}{b} \binom{ta}{n-b} (-1)^{m-a-b} (k-t)^b (x_1-1)^{n-m}$$

for all n . However, if we replace x_1 by $z+1$ in (4.3), we see that the polynomial

$$\sum_{\pi \in [k]^n} (z+1)^{\overleftarrow{\text{des}}_{[t]}(\pi)}$$

has the Laurent expansion

$$\sum_{m \geq 0} \sum_{a=0}^m \sum_{b=0}^{m-a} \binom{m}{a} \binom{m-a}{b} \binom{ta}{n-b} (-1)^{m-a-b} (k-t)^b (z)^{n-m}.$$

It follows that it must be the case that

$$\sum_{m \geq n+1} \sum_{a=0}^m \sum_{b=0}^{m-a} \binom{m}{a} \binom{m-a}{b} \binom{ta}{n-b} (-1)^{m-a-b} (k-t)^b (z)^{n-m} = 0,$$

so that

$$(4.4) \quad A_k = \sum_{n \geq 0} q^n \sum_{m=0}^n \sum_{a=0}^m \sum_{b=0}^{m-a} (-1)^{m-a-b} \binom{m}{a} \binom{m-a}{b} \binom{ta}{n-b} (k-t)^b (x_1-1)^{n-m}.$$

Thus if we take the coefficient of x_1^n on both sides of (4.4) and we use the remark in the introduction that $\overleftarrow{\text{des}}_{[t]}(w) = \overleftarrow{\text{ris}}_{\{k+1-t, \dots, k\}}(w)$ for all $w \in [k]^n$, then we have the following result.

Theorem 4.1. *If $t \leq k$, then the number of words $w \in [k]^n$ such that $\overleftarrow{\text{des}}_{[t]}(w) = s$ ($\overleftarrow{\text{ris}}_{\{k+1-t, \dots, k\}}(w) = s$) is equal to*

$$(4.5) \quad \sum_{m=0}^n \sum_{a=0}^m \sum_{b=0}^{m-a} (-1)^{n-a-b-s} \binom{m}{a} \binom{m-a}{b} \binom{ta}{n-b} \binom{n-m}{s} (k-t)^b.$$

If we want to find formulas for the number of words in $[k]^n$ with s descents that start with an element greater than t , then we need to set $x_1 = y_1 = y_2 = z_1 = z_2 = 1$ and $q_1 = q_2 = q$ in (4.1). In that case, we will have $\lambda_j = 0$ and $\nu_j = q$ for all j , $\mu_j = 1 + q(x_2 - 1)$ for $j > t$, and $\mu_j = 1$ for $j \leq t$. It follows that

$$\begin{aligned} A_k &= \frac{1}{1 - \left(\sum_{j=0}^t q(1 + q(x_2 - 1))^{k-t} + \sum_{j=t+1}^k q \prod_{i=j+1}^k (1 + q(x_2 - 1)) \right)} \\ &= \frac{1}{1 - \left(qt(1 + q(x_2 - 1))^{k-t} + q \frac{(1+q(x_2-1))^{k-t}-1}{(1+q(x_2-1))-1} \right)} \\ &= \frac{1}{1 - \frac{1}{(x_2-1)} (qt(x_2-1)(1+q(x_2-1))^{k-t} + (1+q(x_1-1))^{k-t} - 1)} \\ &= \frac{1}{1 - \frac{1}{(x_2-1)} ((qt(x_2-1)+1)(1+q(x_2-1))^{k-t} - 1)} \\ &= \sum_{m \geq 0} \frac{1}{(x_2-1)^m} ((qt(x_2-1)+1)(1+q(x_2-1))^{k-t} - 1)^m \\ &= \sum_{m \geq 0} \frac{1}{(x_2-1)^m} \sum_{a=0}^m \binom{m}{a} (-1)^{m-a} (qt(x_2-1)+1)^a (1+q(x_2-1))^{(k-t)a} \\ &= \sum_{m \geq 0} \frac{1}{(x_2-1)^m} \sum_{a=0}^m \sum_{b=0}^a \sum_{c=0}^{(k-t)a} (-1)^{m-a} \binom{m}{a} \binom{a}{b} \binom{(k-t)a}{c} q^b t^b (x_2-1)^b q^c (x_2-1)^c. \end{aligned}$$

Again, if we want to take the coefficient of q^n , then we must have $b + c = n$ or $c = n - b$. Thus

$$(4.6) \quad A_k = \sum_{n \geq 0} q^n \sum_{m \geq 0} \sum_{a=0}^m \sum_{b=0}^a (-1)^{m-a} \binom{m}{a} \binom{a}{b} \binom{(k-t)a}{n-b} t^b (x_2-1)^n.$$

Taking the coefficient of q^n of both sides of (4.6), we see that

$$(4.7) \quad \sum_{\pi \in [k]^n} x_2^{\overleftarrow{\text{des}}_{\{t+1, \dots, k\}}(\pi)} = \sum_{m \geq 0} \sum_{a=0}^m \sum_{b=0}^a (-1)^{m-a} \binom{m}{a} \binom{a}{b} \binom{(k-t)a}{n-b} t^b (x_2-1)^{n-m}$$

for all n . However, if we replace x_2 by $z + 1$ in (4.3), we see that the polynomial

$$\sum_{\pi \in [k]^n} (z+1)^{\overleftarrow{\text{des}}_{\{t+1, \dots, k\}}(\pi)}$$

has the Laurent expansion

$$\sum_{m \geq 0} \sum_{a=0}^m \sum_{b=0}^a (-1)^{m-a} \binom{m}{a} \binom{a}{b} \binom{(k-t)a}{n-b} t^b (z)^{n-m}.$$

It follows that it must be the case that

$$\sum_{m \geq n+1} \sum_{a=0}^m \sum_{b=0}^a (-1)^{m-a} \binom{m}{a} \binom{a}{b} \binom{(k-t)a}{n-b} t^b (z)^{n-m} = 0,$$

so that

$$(4.8) \quad A_k = \sum_{n \geq 0} q^n \sum_{m=0}^n \sum_{a=0}^m \sum_{b=0}^a (-1)^{m-a} \binom{m}{a} \binom{a}{b} \binom{(k-t)a}{n-b} t^b (x_1 - 1)^{n-m}.$$

Thus if we take the coefficient of x_2^s on both sides of (4.8) and we use the remark in the introduction that $\overleftarrow{\text{des}}_{\{t+1, \dots, k\}}(w) = \overleftarrow{\text{ris}}_{[k-t]}(w)$ for all $w \in [k]^n$, then we have the following result.

Theorem 4.2. *If $t \leq k$, then the number of words $w \in [k]^n$ such that $\overleftarrow{\text{des}}_{\{t+1, \dots, k\}}(w) = s$ ($\overleftarrow{\text{ris}}_{[k-t]}(w) = s$) is equal to*

$$(4.9) \quad \sum_{m=0}^n \sum_{a=0}^m \sum_{b=0}^a (-1)^{n-a-s} \binom{m}{a} \binom{a}{b} \binom{(k-t)a}{n-b} \binom{n-m}{s} t^b.$$

We end this section by showing that we can derive some non-trivial binomial identities from Theorem 4.1 and 4.2. For example, in the special case of Theorem 4.2 where $t = k-1$, we can count the number of words $w \in [k]^n$ such that $\overleftarrow{\text{des}}_{\{k\}}(w) = s$ directly. We can classify the words in $[k]^n$ by how many k 's occur in the word. That is, for those words $w \in [k]^n$ which have $n-r$ occurrences of k , we can form a word such that $\overleftarrow{\text{des}}_{\{k\}}(w) = s$ by first picking a word $u \in [k-1]^r$. Next we insert a k directly in front of s different letters in u in $\binom{r}{s}$ ways. Finally we can place the remaining $n-r-s$ k 's either in a block with one of the k 's that start a descent or at the end of u . The number ways to place the remaining k 's is the number non-negative integer valued solutions to $x_1 + \dots + x_{s+1} = n-r-s$ or, equivalently, the number of positive integer valued solutions to $y_1 + \dots + y_{s+1} = n-r+1$ which is clearly $\binom{n-r}{s}$. Note that to have s such descents, we must have $r \geq s$ and $n-r \geq s$ or, equivalently, $s \leq r \leq n-s$. It follows that the number of words $w \in [k]^n$ such that $\overleftarrow{\text{des}}_{\{k\}}(w) = s$ equals

$$(4.10) \quad \sum_{r=s}^{n-s} (k-1)^r \binom{r}{s} \binom{n-r}{s}.$$

Using (4.9) with $t = k-1$, we see that (4.10) equals

$$(4.11) \quad \begin{aligned} & \sum_{m=0}^n \sum_{a=0}^m \sum_{b=0}^a (-1)^{n-a-s} \binom{m}{a} \binom{a}{b} \binom{n-m}{s} (k-1)^b = \\ & \sum_{b=0}^n (k-1)^b \sum_{m=0}^n \sum_{a=b}^m (-1)^{n-a-s} \binom{m}{a} \binom{a}{b} \binom{n-m}{s}. \end{aligned}$$

However, in (4.11), we must have $n-m \geq s$ or, equivalently, $n-s \geq m$. Since $m \geq a \geq b$, we must have $b \geq s$ since otherwise the binomial coefficient $\binom{a}{n-b}$ will equal 0. Thus (4.10) equals

$$(4.12) \quad \sum_{b=s}^{n-s} (k-1)^b \sum_{m=b}^{n-s} \sum_{a=b}^m (-1)^{n-a-s} \binom{m}{a} \binom{a}{b} \binom{n-m}{s}.$$

Since (4.10) and (4.12) hold for all k , it follows that

$$(4.13) \quad \sum_{r=s}^{n-s} x^r \binom{r}{s} \binom{n-r}{s} = \sum_{b=s}^{n-s} x^b \sum_{m=0}^n \sum_{a=b}^m (-1)^{n-a-s} \binom{m}{a} \binom{a}{b} \binom{a}{n-b} \binom{n-m}{s}.$$

Thus we have proved that the following identity holds.

$$(4.14) \quad \binom{r}{s} \binom{n-r}{s} = \sum_{m=r}^{n-s} \sum_{a=r}^m (-1)^{n-a-s} \binom{m}{a} \binom{a}{r} \binom{a}{n-r} \binom{n-m}{s}.$$

Next consider the special case of Theorem 4.1 where $t = 2$. Suppose we want to count the number of $\pi \in [k]^n$ where $\overleftarrow{\text{des}}_{[2]}(\pi) = s$. We can classify such words according to number a of 1's and the number b of 2's that appear in the word. Clearly since the only descents that we can count are cases where there is a 2 followed by a 1, we must have $a, b \geq s$. We claim that we can count such words as follows. First we pick word w of length $n - a - b$ made up of letters from $\{3, \dots, k\}$ in $(k-2)^{n-a-b}$ ways. Then to create the s 2 1 descents, we imagine inserting letters of the form $\overline{21}$ into w to get a word u of length $n - a - b + s$ over the alphabet $\{\overline{21}, 3, \dots, k\}$. This can be done in $\binom{n-a-b+s}{s}$ ways. For each such u , we first insert the remaining $a - s$ 1's to get word v of length $n - a - b + s + a - s = n - b$ over the alphabet $\{1, \overline{21}, 3, \dots, k\}$. Since we can insert the 1's in front of any of the letters of u over the alphabet $\{\overline{21}, 3, \dots, k\}$ or at the end, the number of ways to insert the remaining 1's is the number of nonnegative integer solutions to $x_1 + \dots + x_{n-a-b+s+1} = a - s$ which is $\binom{n-b}{a-s}$. Finally, we have to insert the remaining $b - s$ 2's. In this case, since we can insert the 2's into v in front of any letter which is not a 1 or at the end, the number of ways to insert the remaining 2's is the number of nonnegative integer solutions to $x_1 + \dots + x_{n-a-b+s+1} = b - s$ which is $\binom{n-a}{b-s}$. Thus it follows that the number of words $\pi \in [k]^n$ such that $\overleftarrow{\text{des}}_{[2]}(\pi) = s$ is

$$(4.15) \quad \sum_{\substack{a,b \geq s \\ a+b \leq n}} (k-2)^{n-a-b} \binom{n-a-b+s}{s} \binom{n-b}{a-s} \binom{n-a}{b-s}.$$

On the other hand, from Theorem 4.1, we see that the number of words $\pi \in [k]^n$ such that $\overleftarrow{\text{des}}_{[2]}(\pi) = s$ is

$$(4.16) \quad \sum_{m=0}^n \sum_{a=0}^m \sum_{b=0}^{m-a} (-1)^{n-a-b-s} \binom{m}{a} \binom{m-a}{b} \binom{2a}{n-b} \binom{n-m}{s} (k-2)^b.$$

Since (4.15) and (4.16) hold for all k , it must be the case that

$$(4.17) \quad \begin{aligned} & \sum_{\substack{a,b \geq s \\ a+b \leq n}} x^{n-a-b} \binom{n-a-b+s}{s} \binom{n-b}{a-s} \binom{n-a}{b-s} \\ &= \sum_{m=0}^n \sum_{a=0}^m \sum_{b=0}^{m-a} (-1)^{n-a-b-s} \binom{m}{a} \binom{m-a}{b} \binom{2a}{n-b} \binom{n-m}{s} x^b. \end{aligned}$$

Taking the coefficient of x^r on both sides yields the following identity.

$$(4.18) \quad \sum_{r=s}^{n-s} \binom{r+s}{s} \binom{a+r}{a-s} \binom{n-a}{n-a-r-s} = \sum_{m=0}^n \sum_{a=0}^{m-r} (-1)^{n-a-r-s} \binom{m}{a} \binom{m-a}{r} \binom{2a}{n-r} \binom{n-m}{s}.$$

5. CLASSIFYING DESCENTS AND RISES BY THEIR EQUIVALENCE CLASSES mod s FOR $s \geq 2$.

In this section we study the set partition $\mathbb{N} = \mathbb{N}_1 \cup \mathbb{N}_2 \cup \dots \cup \mathbb{N}_s$ where $s > 2$ and $\mathbb{N}_i = \{j \mid j = i \pmod{s}\}$ for $i = 1, \dots, s$. In this case, we shall denote $N_i = s\mathbb{N} + i$ for $i = 1, \dots, s-1$ and $N_s = s\mathbb{N}$.

Recall that we can rewrite (2.7) as

$$(5.1) \quad A_k = \frac{1 + \sum_{j=1}^k \lambda_j \prod_{i=j+1}^k \mu_i}{1 - \sum_{j=1}^k \nu_j \prod_{i=j+1}^k \mu_i}$$

where $\lambda_j = \frac{q_j(1-y_j)}{1-q_j(z_j-y_j)}$, $\mu_i = \frac{q_i(z_i-x_i)}{1-q_i(z_i-y_i)}$, and $\nu_j = \frac{q_j y_j}{1-q_j(z_j-y_j)}$.

We let $A_k^{(s)}$ denote A_k under the substitution that $\lambda_{si+j} = \lambda_j$, $\mu_{si+j} = \mu_j$, and $\nu_{si+j} = \nu_j$ for all i and $j = 1, \dots, s$. Then it is easy to see that for $k \geq 1$,

$$\begin{aligned} A_{sk}^{(s)} &= \frac{1 + \left(\sum_{j=1}^s \lambda_j \prod_{i=j+1}^k \mu_i\right) \left(\sum_{r=0}^{k-1} (\mu_1 \mu_2 \cdots \mu_s)^r\right)}{1 - \left(\sum_{j=1}^s \nu_j \prod_{i=j+1}^k \mu_i\right) \left(\sum_{r=0}^{k-1} (\mu_1 \mu_2 \cdots \mu_s)^r\right)} \\ &= \frac{1 + \left(\sum_{j=1}^s \lambda_j \prod_{i=j+1}^k \mu_i\right) \left(\frac{(\mu_1 \mu_2 \cdots \mu_s)^k - 1}{(\mu_1 \mu_2 \cdots \mu_s) - 1}\right)}{1 - \left(\sum_{j=1}^s \nu_j \prod_{i=j+1}^k \mu_i\right) \left(\frac{(\mu_1 \mu_2 \cdots \mu_s)^k - 1}{(\mu_1 \mu_2 \cdots \mu_s) - 1}\right)}. \end{aligned}$$

More generally, we can express $A_k^{(s)}$ in the form

$$A_k^{(s)} = \frac{\Theta(\lambda_1, \dots, \lambda_k, \mu_1, \dots, \mu_k)}{\Theta(-\nu_1, \dots, -\nu_k, \mu_1, \dots, \mu_k)}$$

where

$$(5.2) \quad \Theta(\lambda_1, \dots, \lambda_k, \mu_1, \dots, \mu_k) = 1 + \left(\sum_{j=1}^k \lambda_j \prod_{i=j+1}^k \mu_i \right) \left(\sum_{r=0}^{k-1} (\mu_1 \mu_2 \cdots \mu_s)^r \right).$$

Then for $1 \leq t < s$, we have that

$$\begin{aligned} (5.3) \quad &\Theta(\lambda_1, \dots, \lambda_k, \mu_1, \dots, \mu_k) \\ &= 1 + \left(\sum_{j=1}^t \lambda_j \prod_{i=j+1}^t \mu_i \right) \left(\sum_{r=0}^k (\mu_1 \mu_2 \cdots \mu_s)^r \right) + (\mu_1 \mu_2 \cdots \mu_t) \left(\sum_{j=1}^{t+1} \lambda_j \prod_{i=j+1}^s \mu_i \right) \left(\sum_{r=0}^{k-1} (\mu_1 \mu_2 \cdots \mu_s)^r \right) \\ &= 1 + \left(\sum_{j=1}^t \lambda_j \prod_{i=j+1}^t \mu_i \right) \left(\frac{(\mu_1 \mu_2 \cdots \mu_s)^{k+1} - 1}{(\mu_1 \mu_2 \cdots \mu_s) - 1} \right) + (\mu_1 \mu_2 \cdots \mu_t) \left(\sum_{j=1}^{t+1} \lambda_j \prod_{i=j+1}^s \mu_i \right) \left(\frac{(\mu_1 \mu_2 \cdots \mu_s)^k - 1}{(\mu_1 \mu_2 \cdots \mu_s) - 1} \right). \end{aligned}$$

Hence, for $1 \leq t \leq s$,

$$(5.4) \quad \begin{aligned} &A_{sk+t}^{(s)} = \\ &\frac{1 + \left(\sum_{j=1}^t \lambda_j \prod_{i=j+1}^t \mu_i \right) \left(\frac{(\mu_1 \mu_2 \cdots \mu_s)^{k+1} - 1}{(\mu_1 \mu_2 \cdots \mu_s) - 1} \right) + (\mu_1 \mu_2 \cdots \mu_t) \left(\sum_{j=1}^{t+1} \lambda_j \prod_{i=j+1}^s \mu_i \right) \left(\frac{(\mu_1 \mu_2 \cdots \mu_s)^k - 1}{(\mu_1 \mu_2 \cdots \mu_s) - 1} \right)}{1 - \left(\sum_{j=1}^t \nu_j \prod_{i=j+1}^t \mu_i \right) \left(\frac{(\mu_1 \mu_2 \cdots \mu_s)^{k+1} - 1}{(\mu_1 \mu_2 \cdots \mu_s) - 1} \right) - (\mu_1 \mu_2 \cdots \mu_t) \left(\sum_{j=1}^{t+1} \nu_j \prod_{i=j+1}^s \mu_i \right) \left(\frac{(\mu_1 \mu_2 \cdots \mu_s)^k - 1}{(\mu_1 \mu_2 \cdots \mu_s) - 1} \right)}. \end{aligned}$$

5.1. The case where k is equal to 0 mod s . First we shall consider formulas for the number of words in $[sk]^n$ with p descents whose first element is equivalent to $r \pmod{s}$ where $1 \leq r \leq s$. Note that if we consider the complement map $\text{comp}_{sk} : [sk]^n \rightarrow [sk]^n$ given by $\text{comp}(\pi_1 \cdots \pi_n) = (sk+1-\pi_1) \cdots (sk+1-\pi_n)$, then it is easy to see that $\overleftarrow{\text{des}}_{s\mathbb{N}+r}(\pi) = \overleftarrow{\text{ris}}_{s\mathbb{N}+s+1-r}(\text{comp}_{sk}(\pi))$ for $r = 1, \dots, s$. Thus the problem of counting the number of words in $[sk]^n$ with p descents whose first element is equivalent to $r \pmod{s}$ is the same as counting the number of words in $[sk]^n$ with p rises whose first element is equivalent to $s+1-r \pmod{s}$.

Now consider the case where $z_i = y_i = 1$ and $q_i = q$ for $i = 1, \dots, s$ and $x_i = 1$ for $i \neq r$. In this case,

$$A_{sk}^{(s)} = \sum_{n \geq 0} q^n \sum_{\pi \in [sk]^n} x_r^{\overleftarrow{\text{des}}_{s\mathbb{N}+r}(\pi)}.$$

Substituting into our formulas for $A_{sk}^{(s)}$, we see that in this case $\lambda_i = 0$ and $\nu_i = q$ for $i = 1, \dots, s$ and $\mu_i = 1$ for $i \neq r$ and $\mu_r = 1 + q(x_r - 1)$. Thus under this substitution, (5.2) becomes

$$\begin{aligned} (5.5) \quad & A_{sk}^{(s)} \\ &= \frac{1}{1 - ((r-1)q\mu_r + (s-r+1)q)\frac{\mu_r^k - 1}{q(x_r - 1)}} \\ &= \frac{1}{1 - \frac{1}{(x_r - 1)}(s + (s-1)q(x_r - 1))(\mu_r^k - 1)} \\ &= \sum_{j=0}^{\infty} \frac{1}{(x_r - 1)^j} (s + (r-1)q(x_r - 1))^j \mu_r^k - 1)^j \\ &= \sum_{j=0}^{\infty} \frac{1}{(x_r - 1)^j} \sum_{i_1, i_2=0}^j \binom{j}{i_1} s^{j-i_1} (r-1)^{i_1} q^{i_1} (x_r - 1)^{i_1} \binom{j}{i_2} (-1)^{j-i_2} \mu_r^{ki_2} \\ &= \sum_{j=0}^{\infty} \frac{1}{(x_r - 1)^j} \sum_{i_1, i_2=0}^j \binom{j}{i_1} s^{j-i_1} (r-1)^{i_1} q^{i_1} (x_r - 1)^{i_1} \binom{j}{i_2} (-1)^{j-i_2} \left(\sum_{t=0}^{ki_2} \binom{ki_2}{t} q^t (x_r - 1)^t \right). \end{aligned}$$

Taking the coefficient of q^n in (5.5), we see that $n = t + i_1$ so that

$$(5.6) \quad A_{sk}^{(s)} = \sum_{n \geq 0} q^n \sum_{j=0}^{\infty} \sum_{i_1, i_2=0}^j (-1)^{j-i_2} s^{j-i_1} (r-1)^{i_1} \binom{j}{i_1} \binom{j}{i_2} \binom{ki_2}{n-i_1} (x_r - 1)^{n-j}.$$

Thus we must have

$$(5.7) \quad \sum_{\pi \in [sk]^n} x_r^{\overleftarrow{\text{des}}_{s\mathbb{N}+r}(\pi)} = \sum_{j=0}^{\infty} \sum_{i_1, i_2=0}^j (-1)^{j-i_2} s^{j-i_1} (r-1)^{i_1} \binom{j}{i_1} \binom{j}{i_2} \binom{ki_2}{n-i_1} (x_r - 1)^{n-j}$$

for all n . However, if we replace x_r by $z+1$ in (5.7), we see that the polynomial

$$\sum_{\pi \in [sk]^n} (z+1)^{\overleftarrow{\text{des}}_{s\mathbb{N}+r}(\pi)}$$

has the Laurent expansion

$$\sum_{j=0}^{\infty} \sum_{i_1, i_2=0}^j (-1)^{j-i_2} s^{j-i_1} (r-1)^{i_1} \binom{j}{i_1} \binom{j}{i_2} \binom{ki_2}{n-i_1} (z)^{n-j}.$$

It follows that it must be the case that

$$\sum_{j=n+1}^{\infty} \sum_{i_1, i_2=0}^j (-1)^{j-i_2} s^{j-i_1} (s-1)^{i_1} \binom{j}{i_1} \binom{j}{i_2} \binom{ki_2}{n-i_1} (z)^{n-j} = 0$$

so that

$$(5.8) \quad A_{sk}^{(s)} = \sum_{n \geq 0} q^n \sum_{j=0}^n \sum_{i_1, i_2=0}^j (-1)^{j-i_2} s^{j-i_1} (s-1)^{i_1} \binom{j}{i_1} \binom{j}{i_2} \binom{ki_2}{n-i_1} (x_r - 1)^{n-j}.$$

Thus we have the following theorem by taking the coefficient of x_r^p on both sides of (5.8).

Theorem 5.1. *The number of words $\pi \in [sk]^n$ with $\overleftarrow{\text{des}}_{s\mathbb{N}+r}(\pi) = p$ ($\overleftarrow{\text{ris}}_{s\mathbb{N}+s+1-r}(\pi) = p$) is*

$$(5.9) \quad \sum_{j=0}^n \sum_{i_1, i_2=0}^j (-1)^{n+p+i_2} s^{j-i_1} (s-1)^{i_1} \binom{j}{i_1} \binom{j}{i_2} \binom{ki_2}{n-i_1} \binom{n-j}{p}.$$

In the case $s = 2$, our formulas simplify somewhat. For example, putting $s = 2$ and $r = 2$ in Theorem 5.1, we obtain the following.

Corollary 5.2. *The number of n -letter words π on $[2k]$ having $\overleftarrow{\text{des}}_E(\pi) = p$ (resp. $\overleftarrow{\text{ris}}_O(\pi) = p$) is given by*

$$\sum_{j=0}^n \sum_{i_1, i_2=0}^j (-1)^{n+p+i_2} 2^{j-i_1} \binom{j}{i_1} \binom{j}{i_2} \binom{ki_2}{n-i_1} \binom{n-j}{p}.$$

Similarly, putting $s = 2$ and $r = 1$ in Theorem 5.1, we obtain the following.

Corollary 5.3. *The number of n -letter words π on $[2k]$ having $\overleftarrow{\text{des}}_O(\pi) = p$ (resp. $\overleftarrow{\text{rise}}_E(\pi) = p$) is given by*

$$\sum_{j=0}^n \sum_{i=0}^j (-1)^{n+p+i} 2^j \binom{j}{i} \binom{i}{n} \binom{n-j}{p}.$$

5.2. The cases where k is equal to $t \bmod s$ for $t = 1, \dots, s-1$. Fix t where $1 \leq t \leq s-1$. First we shall consider formulas for the number of words in $[sk+t]^n$ with p descents whose first element is equivalent to $r \bmod s$ where $1 \leq r \leq s$. We shall see that we have to divide this problem into two cases depending on whether $r \leq t$ or $r > t$. Note that if we consider the complement map $\text{comp}_{sk+t} : [sk+t]^n \rightarrow [sk+t]^n$ given by $\text{comp}(\pi_1 \cdots \pi_n) = (sk+t+1-\pi_1) \cdots (sk+t+1-\pi_n)$, then it is easy to see that $\overleftarrow{\text{des}}_{s\mathbb{N}+r}(\pi) = \overleftarrow{\text{ris}}_{s\mathbb{N}+t+1-r}(\text{comp}_{sk}(\pi))$ for $r = 1, \dots, t$ and $\overleftarrow{\text{des}}_{s\mathbb{N}+r}(\pi) = \overleftarrow{\text{ris}}_{s\mathbb{N}+s+r-t-1}(\text{comp}_{sk}(\pi))$ for $r = t+1, \dots, s$.

First consider the case where $y_i = z_i = 1$ for $i = 1, \dots, s$ and $x_i = 1$ for $i \neq r$ where $r > t$. In this case,

$$A_{sk+t}^{(s)} = \sum_{n \geq 0} q^n \sum_{\pi \in [sk+t]^n} x_r^{\overleftarrow{\text{des}}_{s\mathbb{N}+r}(\pi)}.$$

Substituting into our formulas for $A_{sk+t}^{(s)}$, we see that in this case $\lambda_i = 0$ and $\nu_i = q$ for $i = 1, \dots, s$ and $\mu_i = 1$ for $i \neq r$ and $\mu_r = 1 + q(x_r - 1)$. Thus under this substitution, (5.2) becomes

$$\begin{aligned}
(5.10) \quad & A_{sk+t}^{(s)} \\
&= \frac{1}{1 - qt \frac{\mu_r^{k+1} - 1}{q(x_r - 1)} - ((r - 1 - t)q\mu_r + (s - r + 1)q) \frac{\mu_r^k - 1}{q(x_r - 1)}} \\
&= \frac{1}{1 - \frac{1}{(x_r - 1)}[t\mu_r^{k+1} - 1] + (s - t + (r - 1 - t)q(x_r - 1))(\mu_r^k - 1)} \\
&= \frac{1}{1 - \frac{1}{(x_r - 1)}[\mu_r^k[s + (r - 1)q(x_r - 1)] - [s + (r - 1 - t)q(x_r - 1)]]} \\
&= \sum_{m=0}^{\infty} \frac{1}{(x_r - 1)^m} [\mu_r^k[s + (r - 1)q(x_r - 1)] - [s + (r - 1 - t)q(x_r - 1)]]^m \\
&= \sum_{m=0}^{\infty} \sum_{j=0}^m \frac{(-1)^{m-j}}{(x_r - 1)^m} \binom{m}{j} (s + (r - 1 - t)q(x_r - 1))^{m-j} (s + (r - 1)q(x_r - 1))^j \mu_r^{kj}.
\end{aligned}$$

Using the expansions

$$\begin{aligned}
(s + (r - 1 - t)q(x_r - 1))^{m-j} &= \sum_{i_1=0}^{m-j} \binom{m-j}{i_1} s^{m-j-i_1} (r - 1 - t)^{i_1} q^{i_1} (x_r - 1)^{i_1}, \\
(s + (r - 1)q(x_r - 1))^j &= \sum_{i_2=0}^j \binom{j}{i_2} s^{j-i_2} (r - 1)^{i_2} q^{i_2} (x_r - 1)^{i_2}, \text{ and} \\
\mu_r^{kj} &= \sum_{i_3=0}^{kj} \binom{kj}{i_3} q^{i_3} (x_r - 1)^{i_3},
\end{aligned}$$

and setting $i_1 + i_2 + i_3 = n$, we see that (5.10) becomes

$$(5.11) \quad A_{sk+t}^{(s)} = \sum_{n \geq 0} q^n \sum_{m=0}^{\infty} \sum_{i_1=0}^{m-j} \sum_{i_2=0}^j (-1)^{m-j} s^{m-i_1-i_2} (r - 1 - t)^{i_1} (r - 1)^{i_2} \binom{m}{j} \binom{m-j}{i_1} \binom{j}{i_2} \binom{kj}{n-i_1-i_2} (x_r - 1)^{n-m}.$$

Thus we must have

$$\begin{aligned}
(5.12) \quad & \sum_{\pi \in [sk_t]^n} x_r^{\overleftarrow{\text{des}}_{s\mathbb{N}+r}(\pi)} \\
&= \sum_{m=0}^{\infty} \sum_{i_1=0}^{m-j} \sum_{i_2=0}^j (-1)^{m-j} s^{m-i_1-i_2} (r - 1 - t)^{i_1} (r - 1)^{i_2} \binom{m}{j} \binom{m-j}{i_1} \binom{j}{i_2} \binom{kj}{n-i_1-i_2} (x_r - 1)^{n-m}.
\end{aligned}$$

for all n . However, if we replace x_r by $z + 1$ in (5.12), we see that the polynomial

$$\sum_{\pi \in [sk+t]^n} (z + 1)^{\overleftarrow{\text{des}}_{s\mathbb{N}+r}(\pi)}$$

has the Laurent expansion

$$\sum_{m=0}^{\infty} \sum_{i_1=0}^{m-j} \sum_{i_2=0}^j (-1)^{m-j} s^{m-i_1-i_2} (r-1-t)^{i_1} (r-1)^{i_2} \binom{m}{j} \binom{m-j}{i_1} \binom{j}{i_2} \binom{kj}{n-i_1-i_2} (z)^{n-m}.$$

It follows that it must be the case that

$$\sum_{m=n+1}^{\infty} \sum_{i_1=0}^{m-j} \sum_{i_2=0}^j (-1)^m - j s^{m-i_1-i_2} (r-1-t)^{i_1} (r-1)^{i_2} \binom{m}{j} \binom{m-j}{i_1} \binom{j}{i_2} \binom{kj}{n-i_1-i_2} (x_r - 1)^{n-m} = 0$$

so that

$$(5.13) \quad A_{sk+t}^{(s)} = \sum_{m=0}^n \sum_{i_1=0}^{m-j} \sum_{i_2=0}^j (-1)^{m-j} s^{m-i_1-i_2} (r-1-t)^{i_1} (r-1)^{i_2} \binom{m}{j} \binom{m-j}{i_1} \binom{j}{i_2} \binom{kj}{n-i_1-i_2} (x_r - 1)^{n-m}.$$

Thus we have the following theorem by taking the coefficient of x_r^p on both sides of (5.13).

Theorem 5.4. *If $t = 1, \dots, s-1$ and $t < r \leq s$, then the number of words $\pi \in [sk+t]^n$ with $\overleftarrow{\text{des}}_{s\mathbb{N}+r}(\pi) = p$ ($\overleftarrow{\text{ris}}_{s\mathbb{N}+s+r-t-1}(\pi) = p$) is*

$$(5.14) \quad \sum_{m=0}^n \sum_{i_1=0}^{m-j} \sum_{i_2=0}^j (-1)^{n+p+j} s^{m-i_1-i_2} (r-1-t)^{i_1} (r-1)^{i_2} \binom{m}{j} \binom{m-j}{i_1} \binom{j}{i_2} \binom{kj}{n-i_1-i_2} \binom{n-m}{p}$$

In the case $s = 2$, our formulas simplify somewhat. For example, putting $s = 2$, $r = 2$ and $t = 1$ in Theorem 5.4, we obtain the following.

Corollary 5.5. *The number of n -letter words π over $[2k+1]$ having $\overleftarrow{\text{des}}_E(\pi) = p$ (resp. $\overleftarrow{\text{ris}}_E(\pi) = p$) is given by*

$$\sum_{m=0}^n \sum_{j=0}^m \sum_{i=0}^j (-1)^{n+p+j} 2^{m-i} \binom{m}{j} \binom{j}{i} \binom{kj}{n-i} \binom{n-m}{p}.$$

Next consider the case where $y_i = z_i = 1$ for $i = 1, \dots, s$ and $x_i = 1$ for $i \neq r$ where $r \leq t$. In this case,

$$A_{sk+t}^{(s)} = \sum_{n \geq 0} q^n \sum_{\pi \in [sk+t]^n} x_r^{\overleftarrow{\text{des}}_{s\mathbb{N}+r}(\pi)}.$$

Substituting into our formulas for $A_{sk+t}^{(s)}$, we see that in this case $\lambda_i = 0$ and $\nu_i = q$ for $i = 1, \dots, s$ and $\mu_i = 1$ for $i \neq r$ and $\mu_r = 1 + q(x_r - 1)$. Thus under this substitution, (5.2) becomes

$$\begin{aligned}
(5.15) \quad & A_{sk+t}^{(s)} \\
&= \frac{1}{1 - ((r-1)q\mu_r) + q(t-r+1)\frac{\mu_r^{k+1}-1}{q(x_r-1)} - (s-t)q\mu_r\frac{\mu_r^k-1}{q(x_r-1)}} = \\
&\quad \frac{1}{1 - \frac{1}{(x_r-1)}[(t+(r-1)q(x_r-1))(\mu_r^{k+1}-1) + (s-t)\mu_r(\mu_r^k-1)]} \\
&= \frac{1}{1 - \frac{1}{(x_r-1)}[\mu_r^{k+1}[s+(r-1)q(x_r-1)] - [s+(s-t+r-1)q(x_r-1)]]} \\
&= \sum_{m=0}^{\infty} \frac{1}{(x_r-1)^m} [\mu_r^{k+1}[s+(r-1)q(x_r-1)] - [s+(s-t+r-1)q(x_r-1)]]^m \\
&= \sum_{m=0}^{\infty} \sum_{j=0}^m \frac{(-1)^{m-j}}{(x_r-1)^m} \binom{m}{j} (s+(s-t+r-1)q(x_r-1))^{m-j} (s+(r-1)q(x_r-1))^j \mu_r^{kj+j}.
\end{aligned}$$

Using the expansions

$$\begin{aligned}
(s+(s-t+r-1)q(x_r-1))^{m-j} &= \sum_{i_1=0}^{m-j} \binom{m-j}{i_1} s^{m-j-i_1} (s-t+r-1)^{i_1} q^{i_1} (x_r-1)^{i_1}, \\
(s+(r-1)\mu_r^j) &= \sum_{i_2=0}^j \binom{j}{i_2} s^{j-i_2} (r-1)^{i_2} q^{i_2} (x_r-1)^{i_2}, \text{ and} \\
\mu_r^{kj+j} &= \sum_{i_3=0}^{kj+j} \binom{kj+j}{i_3} q^{i_3} (x_r-1)^{i_3},
\end{aligned}$$

and setting $i_1 + i_2 + i_3 = n$, we see that (5.15) becomes

$$\begin{aligned}
(5.16) \quad & A_{sk+t}^{(s)} = \\
& \sum_{n \geq 0} q^n \sum_{m=0}^{\infty} \sum_{i_1=0}^{m-j} \sum_{i_2=0}^j (-1)^{m-j} s^{m-i_1-i_2} (s-t+r-1)^{i_1} (r-1)^{i_2} \binom{m}{j} \binom{m-j}{i_1} \binom{j}{i_2} \binom{kj+j}{n-i_1-i_2} (x_r-1)^{n-m}.
\end{aligned}$$

Thus we must have

$$\begin{aligned}
(5.17) \quad & \sum_{\pi \in [sk+t]^n} x_r^{\overleftarrow{\text{des}}_{s\mathbb{N}+r}(\pi)} = \\
& \sum_{m=0}^{\infty} \sum_{i_1=0}^{m-j} \sum_{i_2=0}^j (-1)^{m-j} s^{m-i_1-i_2} (s-t+r-1)^{i_1} (r-1)^{i_2} \binom{m}{j} \binom{m-j}{i_1} \binom{j}{i_2} \binom{kj+j}{n-i_1-i_2} (x_r-1)^{n-m}.
\end{aligned}$$

for all n . However, if we replace x_r by $z+1$ in (5.17), we see that the polynomial

$$\sum_{\pi \in [sk+t]^n} (z+1)^{\overleftarrow{\text{des}}_{s\mathbb{N}+r}(\pi)}$$

has the Laurent expansion

$$\sum_{m=0}^{\infty} \sum_{i_1=0}^{m-j} \sum_{i_2=0}^j (-1)^m - j s^{m-i_1-i_2} (s-t+r-1)^{i_1} (r-1)^{i_2} \binom{m}{j} \binom{m-j}{i_1} \binom{j}{i_2} \binom{kj+j}{n-i_1-i_2} (z)^{n-m}.$$

It follows that it must be the case that

$$\sum_{m=n+1}^{\infty} \sum_{i_1=0}^{m-j} \sum_{i_2=0}^j (-1)^{m-j} s^{m-i_1-i_2} (s-t+r-1)^{i_1} (r-1)^{i_2} \binom{m}{j} \binom{m-j}{i_1} \binom{j}{i_2} \binom{kj+j}{n-i_1-i_2} (x_r-1)^{n-m} = 0$$

so that

$$(5.18) \quad A_{sk+t}^{(s)} = \sum_{m=0}^{\infty} \sum_{i_1=0}^{m-j} \sum_{i_2=0}^j (-1)^{m-j} s^{m-i_1-i_2} (s-t+r-1)^{i_1} (r-1)^{i_2} \binom{m}{j} \binom{m-j}{i_1} \binom{j}{i_2} \binom{kj+j}{n-i_1-i_2} (x_r-1)^{n-m}.$$

Thus we have the following theorem by taking the coefficient of x_r^p on both sides of (5.13).

Theorem 5.6. *If $k \geq 0$, $s \geq 2$, $t = 1, \dots, s-1$, and $t < r \leq s$, then the number of words $\pi \in [sk+t]^n$ with $\overleftarrow{\text{des}}_{s\mathbb{N}+r}(\pi) = p$ ($\overleftarrow{\text{ris}}_{s\mathbb{N}+s+r-t-1}(\pi) = p$) is*

$$(5.19) \quad \sum_{m=0}^{\infty} \sum_{i_1=0}^{m-j} \sum_{i_2=0}^j (-1)^{n+p+j} s^{m-i_1-i_2} (s-t+r-1)^{i_1} (r-1)^{i_2} \binom{m}{j} \binom{m-j}{i_1} \binom{j}{i_2} \binom{kj+j}{n-i_1-i_2} \binom{n-m}{p}$$

In the case $s = 2$, our formulas simplify somewhat. For example, putting $s = 2$, $r = 1$ and $t = 1$ in Theorem 5.4, we obtain the following.

Corollary 5.7. *The number of n -letter words π over $[2k+1]$ having $\overleftarrow{\text{des}}_O(\pi) = p$ (resp. $\overleftarrow{\text{ris}}_O(\pi) = p$) is given by*

$$\sum_{m=0}^n \sum_{j=0}^m \sum_{i=0}^{kj+j} (-1)^{n+p+j} 2^{m-n+i} \binom{m}{j} \binom{m-j}{n-i} \binom{jk+j}{i} \binom{n-m}{p}.$$

6. CONCLUDING REMARKS

A particular case of the results obtained by Burstein and Mansour in [4] is the distribution of descents (resp. levels, rises), which can be viewed as occurrences of so called *generalized patterns* 21 (resp. 11, 12) in words. To get these distributions from our results, we proceed as follows (we explain only the case of descents; rises and levels can be considered similarly). Set $x_1 = x_2 = x$, $y_1 = y_2 = z_1 = z_2 = 1$, and $q_1 = q_2 = q$ in $A_{2k}^{(2)}$ and $A_{2k+1}^{(2)}$ to get the distribution in [4, Theorem 2.2] for $\ell = 2$ (the case of descents/rises). Thus, our results refine and generalize the known distributions of descents, levels, and rises in words.

It is interesting to compare our formulas with formulas of Hall and Remmel [7]. For example, suppose that $X = E$ and $Y = \mathbb{N}$ and $\rho = (\rho_1, \dots, \rho_{2k})$ is a composition of n . Then Theorem 1.1 tells that the number of words π of $[2k]^n$ such that $\overleftarrow{\text{des}}_E(\pi) = p$ is

$$(6.1) \quad \binom{a}{\rho_2, \rho_4, \dots, \rho_{2k}} \sum_{r=0}^p (-1)^{p-r} \binom{a+r}{r} \binom{n+1}{p-r} \prod_{i=1}^k \binom{\rho_{2i} + r + (\rho_{2i+1} + \rho_{2i+3} + \dots + \rho_{2k-1})}{\rho_{2i}},$$

where $a = \rho_2 + \rho_4 + \cdots + \rho_{2k}$. This shows that once we are given the distribution of the letters for words in $[2k]^n$, we can find an expression for the number of words π such that $\overleftarrow{\text{des}}_E(\pi) = p$ with a single alternating sum of products of binomial coefficients. This contrasts with Corollary 5.2 where we require a triple alternating sum of products of binomial coefficients to get an expression for the number of words of $[2k]^n$ such that $\overleftarrow{\text{des}}_E(\pi) = p$. Of course, we can get a similar expressions for the number of words of $[2k]^n$ such that $\overleftarrow{\text{des}}_E(\pi) = p$ by summing the formula in (6.1) over all $\binom{n+k-1}{k-1}$ compositions of n into k parts but that has the disadvantage of having the outside sum have a large range as n and k get large. Nevertheless, we note that for (6.1) there can be given a direct combinatorial proof via a sign-reversing involution so that it does not require any use of recursions. It is therefore natural to ask whether one can find similar proofs for our formulas in sections 3 and 4.

There are several ways in which one could extend our research. For example, one can study our refined statistics $(\overleftarrow{\text{Des}}_X(\pi), \overleftarrow{\text{Ris}}_X(\pi), \text{Lev}_X(\pi))$ on the set of all words avoiding a fixed pattern or a set of patterns (see [1, 2, 3, 4] for definitions of “patterns in words” and results on them). More generally, instead of considering the set of all words, one can consider a subset of it defined in some way, and then to study the refined statistics on the subset. Also, instead of considering refined descents, levels, and rises (patterns of length 2), one can consider patterns of length 3 and more in which the equivalence class of the first letter is fixed, or, more generally, in which the equivalence classes of more than one letter (possibly all letters) are fixed. Once such a pattern (or set of patterns) is given, the questions on avoidance (or the distribution of occurrences) of the pattern in words over $[k]$ can be raised.
